

# Lecture 1 - 4<sup>th</sup> Sept 2024

Statistics: the science of understanding data and making decisions in the face of variability and uncertainty.

Probability: A branch of mathematics concerned with describing and modeling uncertain events.

## Preliminaries:

- Experiment: the process of obtaining an observed result of some phenomenon.
- Trial: the performance of an experiment.
- Outcome: the result of a single trial (attempt) of an experiment.
- Event: one or more outcomes of an experiment.
- Probability: the measure of how likely an event is.

Sample Space: the set of ALL possible distinct outcomes in a random experiment, denoted by  $S$ .

↳ note: one and only one of the outcomes occurs in any single trial of the experiment.

↳ example:

- Roll a six-sided die:  $S = \{1, 2, 3, 4, 5, 6\}$
- Flip a coin:  $S = \{\text{heads, tails}\}$
- Waiting time for a bus:  $S = \{t \in \mathbb{R}, 0 \leq t \leq 10\}$
- A sample space is finite if it consists of a

finite number of outcomes, say  $\{a_1, a_2, \dots, a_n\}$

- A sample space can be a set of countable infinite outcomes, say  $\{a_1, a_2, \dots\}$ , where the outcomes can be put into a one-on-one correspondence with positive integers.

↳ Example: suppose our experiment consists of tossing a coin until it lands on heads.

↳ the possible outcomes in the sample space are:

H, TH, TTH, TTTH, TTTTH, ...

∴ the outcomes are countable but infinite.

Discrete Sample Space: when a sample space is either finite or countably infinite. Else, it's non-discrete.

↳ Example:

- Roll a six-sided die: discrete
- Flip a coin: discrete
- Waiting time for a bus: non-discrete

Event: a subset of sample space S.

↳ we say A is an event if  $A \subset S$ .

↳ note: A and S are both sets!

Example: consider tossing two coins.

a) what is the event of obtaining at least one head?

$$S = \{ HH, HT, TH, TT \}$$

$$\therefore A = \{ HH, HT, TH \}$$

b) What is the event of obtaining at least one head and at least one tail?

$$A = \{ HT, TH \}.$$

**Elementary / Simple Event:** an event that contains only one outcome of the experiment. Eg,  $A = \{ \alpha, \beta \}$ .

**Compound Event:** an event made up of two or more simple events. Eg:  $A = \{ \alpha_1, \alpha_2 \}$ .

**Set Notations and Terminology:**

- A set is a collection of elements. Eg,  $A = \{ \text{apple, orange} \}$ .
- The notation  $\alpha \in A$  or  $\alpha \notin A$  will mean that  $\alpha$  is or is not an element of  $A$ .
- The empty / null set is  $\emptyset$ .
- Union:  $A \cup B = \{ \alpha \mid \alpha \in A \text{ or } \alpha \in B \}$
- Intersection:  $A \cap B = \{ \alpha \mid \alpha \in A \text{ and } \alpha \in B \}$
- The notation  $B \subset A$  means that  $B$  is a subset of  $A$ .
- Complement:  $A^c = \{ \alpha \mid \alpha \in S, \alpha \notin A \} = \bar{A}$
- Two sets  $A$  and  $B$  are disjoint if  $A \cap B = \emptyset$ .

- The set  $A \cap B^c$  is "A but not B"
- The set  $A^c \cap B^c$  is "neither A nor B"
- If  $A_1, \dots, A_n$  is a finite collection of sets,

$\rightarrow A_1 \cap \dots \cap A_n = \bigcap_{i=1}^n A_i$  is "in all  $A_i$ ;"

$\rightarrow A_1 \cup \dots \cup A_n = \bigcup_{i=1}^n A_i$  is "in at least one  $A_i$ ;"

*p very similar to disjoint!*

Mutually Exclusiveness: when two events A and B if  $A \cap B = \emptyset$ . If events are exclusive, they have no outcomes in common.

Example: tossing two coins. A is the event "at least one head", and B is the event "both tails".

$$S = \{HH, HT, TH, TT\}.$$

$$A = \{HH, HT, TH\}, B = \{TT\}.$$

$$A \cap B = \{HH, HT, TH\} \cap \{TT\} = \emptyset !$$

$\therefore$ , A and B are mutually exclusive.

Events  $A_1, A_2, A_3, \dots$  are said to be mutually exclusive if they are pairwise mutually exclusive. That is,

$$A_i \cap A_j = \emptyset, \text{ wherever } i \neq j.$$

Probability Modeling : assigning a probability  $P(A)$  to each event  $A$ . This probability measures how likely it is that  $A$  will happen when the experiment is conducted.

- ↳ think of  $P(A)$  as a (set) function, whose domain is a collection of sets (events), and the range of which is a subset of real numbers.
- ↳ not all set functions are appropriate for assigning probabilities to events.

• Let  $S = \{\alpha_1, \alpha_2, \alpha_3, \dots\}$  be a discrete sample space. We assign to each elementary event  $A_i = \{\alpha_i\}$  for  $i = 1, 2, \dots$ , a number  $P(A_i) = P(\{\alpha_i\})$ , such that

- $0 \leq P(A_i)$  and  $\sum_{\text{all } i} P(A_i) = 1$

• We call  $P(A)$  the probability of  $A$ , and call the set of probabilities  $\{P(A_i), i=1, 2, \dots\}$  the probability distribution on  $S$ .

#### ↳ General Properties :

- The null event (empty set) has a probability of 0. ∴  $P(\emptyset) = 0$ .
- If  $A$  and  $B$  are two mutually exclusive events, then  $P(A \cup B) = P(A) + P(B)$
- If  $A_1, A_2, \dots, A_k$  is a finite collection of pairwise mutually exclusive events, then

$$P(A_1 \cup A_2 \cup \dots \cup A_R) = P(A_1) + P(A_2) + \dots + P(A_R)$$

$$\cdot P(\bar{A}) = 1 - P(A)$$

↳ Example: Suppose a six-sided die is rolled once.  
If A is the event that an even number is obtained.  
What is  $P(A)$ ?

- $S: \{1, 2, 3, 4, 5, 6\}$ . Since each number is equally likely,  $P(\{i\}) = \frac{1}{6}$  for  $i = 1, 2, 3, 4, 5, 6$ .

$$A = \{2, 4, 6\} \rightarrow P(A) = P(\{2\}) + P(\{4\}) + P(\{6\}) \\ = \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{3}{6} = \frac{1}{2}.$$

↳ Example: Toss a coin twice. What's the probability of getting exactly one head?

- $S: \{HH, HT, TH, TT\}$ . Each option is uniformly likely.
- $A = \{HT, TH\} \rightarrow P(A) = P(\{HT\}) + P(\{TH\}) \\ = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}.$

**Random Selection:** when choosing an object from a finite set where each object has an equal chance of being selected.

**Uniform Probability Model:** consider a discrete finite sample space  $S = \{a_1, a_2, \dots, a_n\}$ , where each

simple event has a probability of  $\frac{1}{N}$ . This is a uniform distribution over the set  $\{\alpha_1, \alpha_2, \dots, \alpha_N\}$ .

For a compound event A, we can calculate  $P(A)$  by:

$$P(A) = \frac{n(A)}{N},$$

where  $n(A)$  is the number of outcomes in A.

The formula  $P(A) = \frac{n(A)}{N}$  is classical probability.

(trivial) example: draw one card at random from a well-shuffled deck without jokers. What is the probability that the card is a spade?

$$S = \{A\heartsuit, 2\heartsuit, \dots\}.$$

$$A_s = \{A\spadesuit, 2\spadesuit, \dots, K\spadesuit\}.$$

$$P(A_s) = \frac{n(A_s)}{N} = \frac{13}{52} = \frac{1}{4}.$$

Example: suppose that P is a probability, and A and B are events such that A and B are mutually exclusive, and  $P(\bar{A}) = 0.8$  and  $P(\bar{B}) = 0.7$ . Is each statement true or false?

A) A and B are each non-empty

Since  $P(\bar{A}) = 0.8$  and  $P(\bar{B}) = 0.7$ , we know that

$$P(A) = 0.2 \text{ and } P(B) = 0.3.$$

we also know that  $P(\emptyset) = 0$ . Since  $0.2 \neq 0 \neq 0.3$ , we know A and B cannot be empty.  
 $\therefore$  the statement is true.

B)  $P(A \cap B) = 0$

Since we're told that A and B are mutually exclusive, we know that  $A \cap B = \emptyset$ .

we also know that  $P(\emptyset) = 0$ , so the statement is true!

C)  $P(A \cup B) = 0.4$

we know that  $\boxed{P(A \cup B)} = P(A) + P(B)$

"the probability of  
A or B"

$$P(A) + P(B) = 0.2 + 0.3 = 0.5 \neq 0.4.$$

$\therefore$  the statement is false!

Example: suppose two six-sided die are rolled where the outcomes are of the form (die 1, die 2). If A is the event that the first die is even, and B is the event that the sum of both rolls is 6, compute the event  $C = \bar{A} \cap B$

$$\hookrightarrow A = \{(2,1), (2,2), \dots, (4,1), (4,2), \dots, (6,1), (6,2), \dots, (6,6)\}.$$

$$B = \{(1,5), (2,4), (3,3), (4,2), (5,1)\}$$

$\bar{A}$  means the event that A does not happen, so in other words,  $\bar{A}$  is the event that the first die is odd.

$$\therefore \bar{A} = \{(1,1), \dots, (1,6), (3,1), \dots, (3,6), (5,1), \dots, (5,6)\}.$$

$\bar{A} \cap B$  is A AND B.

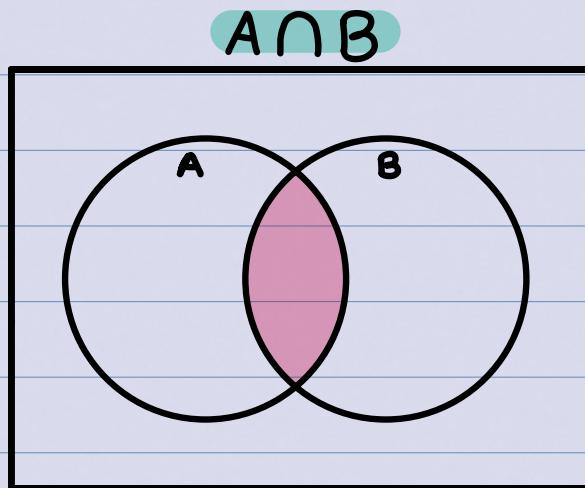

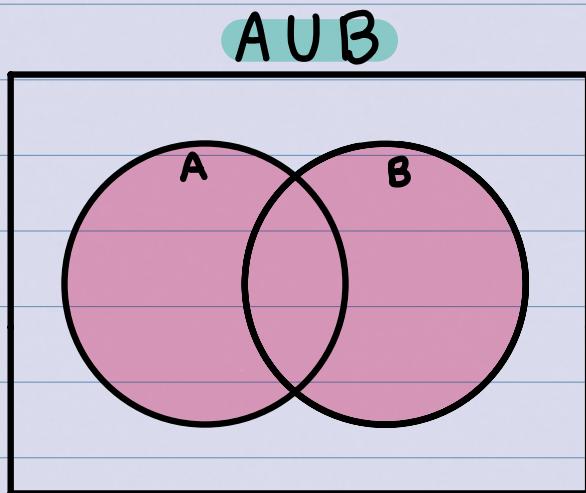

$$\hookrightarrow \therefore C = \{(1,5), (3,3), (5,1)\}.$$

Venn Diagram: a tool to illustrate the relationship among sets (or events).

↳ made up of:

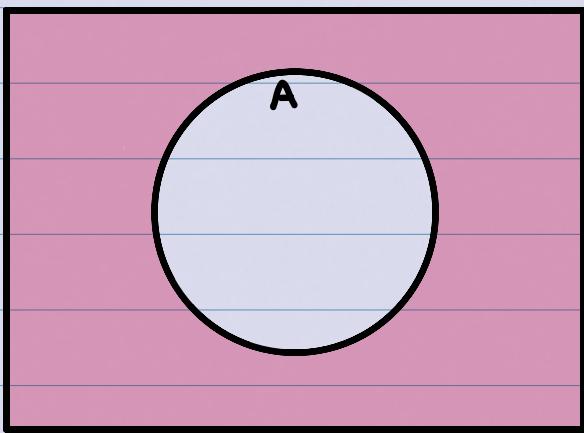

- a rectangle to represent the sample space S.
- Circles within the rectangle to illustrate the events.

## The Union and Intersection of Two Events

## The Compliment of an Event:

$\bar{A}$

"S but not A"

De Morgan's Laws:

$$\cdot \overline{A \cup B} = \bar{A} \cap \bar{B}$$

$$\cdot \overline{A \cap B} = \bar{A} \cup \bar{B}$$

Probability Rules

- Probability of the Complement of an Event
    - $P(A) = 1 - P(\bar{A})$
- Proof:  $A \cup \bar{A} = S$ , so  $P(A \cup \bar{A}) = P(A) + P(\bar{A})$   
since  $P(A \cup \bar{A}) = P(S) = 1$ ,  $1 = P(A) + P(\bar{A})$   
bc mutually exclusive!

Example: an experiment involves tossing a coin four times. The event A is "at least one head". Find the probability of A, ie, find  $P(A)$ .

- the only case where there is NOT at least one head is  $\bar{A} = \{\text{TTTT}\}$ .

flipping a coin 4 times would result in  $2^4$  possible

outcomes, and  $\bar{A}$  is only 1 of these.

$$\therefore P(\bar{A}) = \frac{1}{16}, \text{ so } P(A) = 1 - P(\bar{A}) = 1 - \frac{1}{16} = \frac{15}{16}.$$

probability of complement!

Example: two ordinary dice are rolled. Find the probability that at least one lands on a 6.

$$S = \{(1,1), \dots, (1,6), (2,1), \dots, (2,6), \dots, (6,1), \dots, (6,6)\}.$$

$A$  = the event of at least one six.

$\therefore \bar{A}$  is the event that neither die is a six.

classical probability of each die to NOT be a six:  $\frac{n(x)}{N}$ .

where  $n(x)$  is the number of outcomes that satisfy the roll not being a 6 - ie;  $\{1, 2, 3, 4, 5\} \Rightarrow 5$ , and  $N$  is the total number of outcomes in the set - ie;  $\{1, 2, 3, 4, 5, 6\} \Rightarrow 6$ .

$$\therefore \frac{n(x)}{N} = \frac{5}{6} !$$

since both dice are independent, the probability of both NOT being a six (aka  $\bar{A}$ ) is  $\frac{5}{6} \cdot \frac{5}{6}$ .

$$\therefore P(\bar{A}) = \frac{25}{36}, \text{ so } P(A) = 1 - \frac{25}{36} = \frac{11}{36} !$$

Rules for Union:

• Union of two events:  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

Example: At a university, 70% of the students own a car, 60% of students live on campus, and 50% both live on campus and own a car. If a student is chosen at random, what is the probability that the student does not own a car and does not live on campus?

- Let A be the event that a student has a car.
- Let B be the event that a student lives on campus.

we want:  $P(\bar{A} \cap \bar{B})$ .

↳ we know that  $\bar{A} \cap \bar{B} = \overline{A \cup B}$ .

$$\hookrightarrow P(\bar{A} \cap \bar{B}) = 1 - P(\overline{A \cup B}) = 1 - P(A \cup B)$$

from the union of two events,  $P(A \cup B) = P(A) + P(B) - P(A \cap B)$

$$\begin{aligned}\therefore P(\bar{A} \cap \bar{B}) &= 1 - (P(A) + P(B) - P(A \cap B)) \\ &= 1 + P(A \cap B) - P(A) - P(B) \\ &= 1 + 0.5 - 0.7 - 0.6\end{aligned}$$

$$\hookrightarrow \therefore P(\bar{A} \cap \bar{B}) = 0.2 = 20\%.$$

Union of Three Events: for any 3 events A, B, and C:

$$P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(A \cap B) - P(A \cap C) - P(B \cap C) + P(A \cap B \cap C)$$

**Conditional Probability:** determining the probability of some event A, while knowing that some related event B has occurred.

**Example:** consider that a fair die has been rolled and you are asked to give the probability that it was a 5.

$$\hookrightarrow A = \{5\}, S = \{1, 2, 3, 4, 5, 6\}.$$

$$\therefore P(A) = \frac{n(A)}{n(S)} = \frac{1}{6}.$$

However, if you're told that the dice has landed on an odd number, the odds change:

$$\hookrightarrow A = \{5\}, S = \{1, 3, 5\}.$$

$$\therefore P(A) = \frac{n(A)}{n(S)} = \frac{1}{3}.$$

**Example:** a box contains 100 microchips, some produced by Factory 1 and the rest by Factory 2. Among these microchips, some are defective, while others are good. Let A be the event of "obtaining a defective microchip" and B be the event of "the microchip was produced in Factory 2."

the number of microchips in each category:

	B	$\bar{B}$	totals
A	15	5	20
$\bar{A}$	45	35	80
totals	60	40	100

a) Find the probability of obtaining a defective microchip.

the total of A is 20, and there are 100 total microchips.

$$\hookrightarrow P(A) = \frac{n(A)}{N} = \frac{20}{100} = \frac{1}{5} \quad (20\%)$$

b) Given that a microchip is from factory 1, find the probability that it is defective.

the sample space S shrinks from all 100 microchips to only the 60 made by factory 1 (event B).

$$\hookrightarrow \therefore P(A) = \frac{n(A)}{N} = \frac{15}{60} = \frac{1}{4} \quad (25\%)$$

Conditional Probability mathematical definition:

$$P(A | B) = \frac{P(A \cap B)}{P(B)} \quad (P(B) > 0)$$

↪ "the probability of A given B"

$$\hookrightarrow 0 \leq P(A|B) \leq 1$$

- $P(A|B) = 1 - P(\bar{A}|B)$

Pretty much the same as  
the regular union of two events

- $P(A_1 \cup A_2 | B) = P(A_1|B) + P(A_2|B) - P(A_1 \cap A_2 | B)$

**Multiplication Theorem of Probability:** a way to compute the joint occurrence of A and B:

$$\hookrightarrow P(A \cap B) = P(B) \cdot P(A|B) = P(A) \cdot P(B|A)$$

**Law of Total Probability:** if  $B_1, B_2, \dots, B_k$  is a collection of mutually exclusive events and  $B_1 \cup B_2 \cup \dots \cup B_k = S$ , then for any event A,

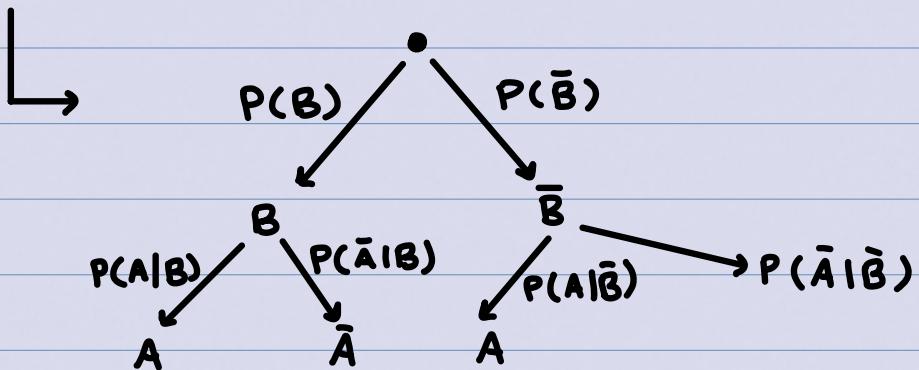

$$P(A) = \sum_{i=1}^k P(B_i) \cdot P(A|B_i)$$

Note: for a special case  $k=2$ :

only for  
 $k=2$  !!

$$P(A) = P(A|B) \cdot P(B) + P(A|\bar{B}) \cdot P(\bar{B})$$

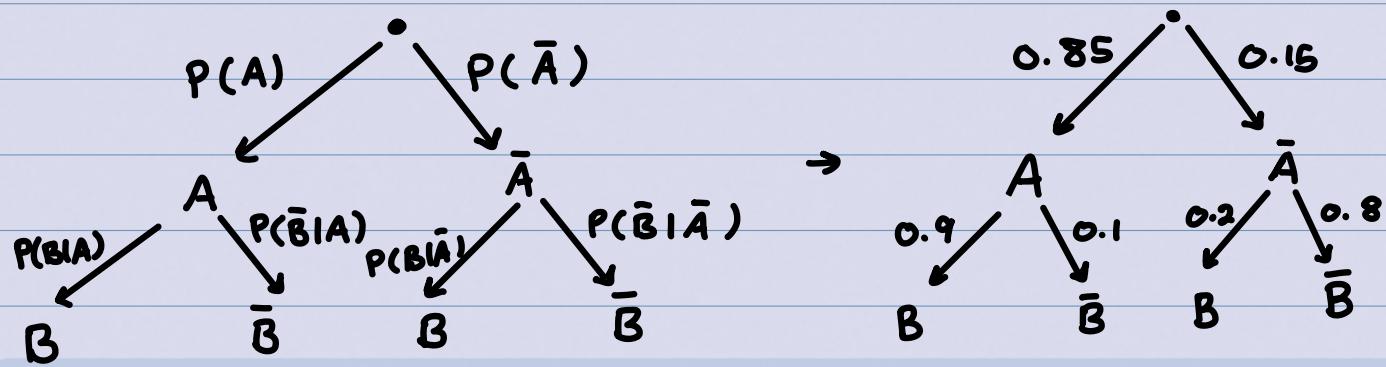

for event A to occur, it must happen with either B or  $\bar{B}$ .  $\therefore$  only  $A \cap B$  or  $A \cap \bar{B}$  can occur.

Example: without water, a plant will die with a

probability of 0.8, and with water, it will die with a probability of 0.1. I'll remember to water the plant with a probability of 0.85. Represent this info using a tree diagram.

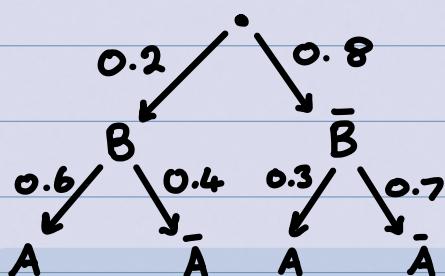

Let A be the event that I remember to water the plant, and B be the event that the plant survives.

Example: in a typical year, 20% of the days have a high temperature greater than  $22^{\circ}\text{C}$ . 40% of these days, there is no rain. During the rest of the year, when the temperature is  $\leq 22^{\circ}\text{C}$ , 70% of the days have no rain.

a) represent this information in a tree diagram.

let A be the event that it rains, and let B be the event that the temperature peaks above  $22^{\circ}\text{C}$ .

b) solve for the proportion of days in the year which have rain and a temperature  $\leq 22^{\circ}\text{C}$ .

↳ aka, find  $P(A \cap \bar{B})$

$$\text{we know } P(A|\bar{B}) = \frac{P(A \cap \bar{B})}{P(\bar{B})} = \frac{P(A \cap \bar{B})}{1 - P(B)}$$

$$\begin{aligned} \therefore P(A \cap \bar{B}) &= P(A|\bar{B}) \cdot (1 - P(B)) \\ &= 0.3 \cdot (1 - 0.2) = 0.3 \cdot 0.8 = 0.24 \\ &= 24\% . \end{aligned}$$

Baye's Rule:  $P(B|A) = \frac{P(A|B)P(B)}{P(A|B)P(B) + P(A|\bar{B})P(\bar{B})}$ ,

and more generally,  $P(B_j|A) = \frac{P(B_j)P(A|B_j)}{\sum_{i=1}^k P(B_i)P(A|B_i)}$  ↗ for each  $j=1, 2, \dots, k$ .

Example: revisiting the plant problem from before, if the plant is alive, what's the probability that I remembered to water it?

↗ same as previous time

↳ let A be the event that I remember to water the plant, and B be the event that the plant survives.

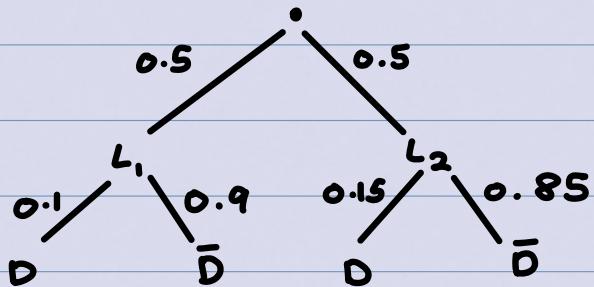

$$\begin{aligned} P(A|B) &= \frac{P(B|A)P(A)}{P(B|A)P(A) + P(B|\bar{A})P(\bar{A})} = \frac{(0.9)(0.85)}{(0.9)(0.85) + (0.2)(0.15)} \\ &= 0.9623 = 96.23\% ! \end{aligned}$$

Example: electric motors from two assembly lines are

pooled in a common stockroom, with equal numbers of motors from each line. Motors are periodically sampled for testing. It's known that 10% of the motors from line 1 are defective, while 15% of the motors from line two are defective.

a) if a motor is randomly selected, what is the probability that it is defective?

Let D be the event that a motor is defective.

$$\begin{aligned} \rightarrow P(D) &= P(D \cap L_1) + P(D \cap L_2) \\ &= 0.5 \cdot 0.1 + 0.5 \cdot 0.15 \\ &= 0.125 \end{aligned}$$

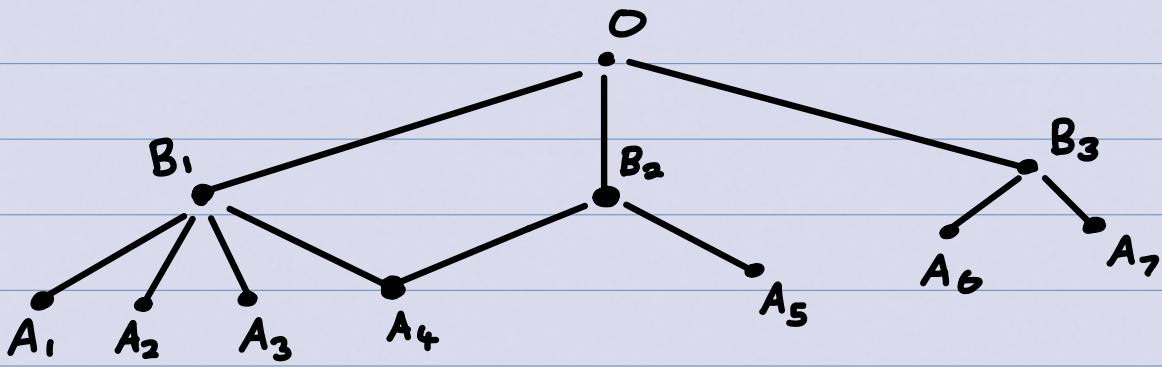

↳ 12.5% chance.

b) if the randomly selected motor is defective, what is the probability that it came from line 1?

$$P(L_1 | D) = \frac{P(D | L_1) P(L_1)}{P(D)} = \frac{0.1 \cdot 0.5}{0.125} = 0.4$$

= 40% chance.

Example: a man starts at point O on this map. He chooses a path at random and follows it to point B<sub>1</sub>, B<sub>2</sub>, or B<sub>3</sub>. From that point, he chooses a new path at random and follows it to one of the points A, ... A<sub>7</sub>.

a) what is the probability that the man arrives at point  $A_4$ ?

$$P(A_4) = P(A_4 | B_1) + P(A_4 | B_2) = \frac{1}{4} \cdot \frac{1}{3} + \frac{1}{2} \cdot \frac{1}{3} = \frac{1}{12} + \frac{1}{6}$$

$$= \frac{1}{4} = 0.25$$

$= 25\%$  !

b) suppose that the man arrives at point  $A_4$ . What is the probability that he passed through  $B_1$ ?

$$P(B_1 | A_4) = \frac{P(A_4 | B_1)}{P(A_4)} = \frac{\frac{1}{4} \cdot \frac{1}{3}}{\frac{1}{4}} = \frac{\frac{1}{12}}{\frac{1}{4}} = \frac{4}{12} = \frac{1}{3}$$

$\therefore$ , there was an 33.33% chance he came from  $B_1$ .

**Independent Event:** events A and B are called independent if and only if  $P(A \cap B) = P(A)P(B)$ . Otherwise, A and B are called dependent events.

↳ an equivalent formulation can be given in terms of conditional probability :

→ If A and B are events such that  $P(A) > 0$  and  $P(B) > 0$ , then A and B are called independent if and only if either of the following hold:

$$P(A|B) = P(A), \text{ or } P(B|A) = P(B)$$

Note: independence  $\neq$  mutually exclusive!

unless  $P(A) = 0$ !

General rule:  $P(A \cap B) = P(B|A) \cdot P(A)$

Independence of Compliments: Suppose events A and B are independent. Then the following events are also independent:

- $\bar{A}$  and  $\bar{B}$
- $\bar{A}$  and B
- A and  $\bar{B}$

Independence of n events: the k events  $A_1, A_2, \dots, A_k$  are said to be independent, or mutually independent, if and only if:

$$P(A_{i_1} \cap A_{i_2} \cap \dots \cap A_{i_k}) = P(A_{i_1}) P(A_{i_2}) \dots P(A_{i_k})$$

forall possible distinct  $i_1, i_2, \dots, i_k$  chosen from 1, 2, ..., n.

→ Note: for a sequence of events to be independent, all of their subsets must also be independent.

Example: suppose a fair die is rolled twice. Let A be the event that the first roll is a 6, and let B be the event

that the second roll is a 6. Show that A and B are independent events.

↳ we want to show that  $P(A \cap B) = P(A) \cdot P(B)$

$$P(\{6,6\}) = P(A \cap B) = \frac{1}{6} \cdot \frac{1}{6} = \frac{1}{36}.$$

$$P(A) = \frac{n(A)}{N} = \frac{1}{6} = \frac{n(B)}{N} = P(B). \therefore P(A) = P(B) = \frac{1}{6}.$$

$$P(A) \cdot P(B) = \frac{1}{36} = P(A \cap B).$$

↳ ∴, the events are independent.

## Counting Techniques

often, manually counting many outcomes manually can be very time-consuming and tedious.

1) Addition Rule : "OR" interpreted as addition

↳ Eg: suppose job 1 can be done in p ways and job 2 can be done in q ways. ∴, we can do either job 1 or job 2 in  $p+q$  ways.

2) Multiplication Rule: "AND" interpreted as multiplication.

↳ Eg: suppose job 1 can be done in p ways and for each of these ways, we can do job 2 in q ways. ∴, we can do both Job 1 and Job 2 in  $p \times q$  ways.

Example: how many are there to answer a 20

## question true/false test?

$$Q_1 \cdot Q_2 \cdot \dots \cdot Q_{20} = 2^{20} \text{ ways.}$$

**Sampling with Replacement:** what we get on the first selection does not affect what we get on second selection.

↳ Eg: every time an object is selected, it's put back into the pool of possible objects.

**Sampling without Replacement:** what we get on the first selection will affect what we get on the second selection.

↳ Eg: once an object is selected, it stays out of the pool of possible objects.

**Example:** A bag contains 3 blue marbles and 5 red marbles. If you pick two marbles from the bag,

a) what is the probability of picking 2 blue marbles if the selection is with replacement?

let A be the event of picking two marbles.

↳  $P(A) = P(\text{blue on first pick}) + P(\text{blue on second pick})$

$$\hookrightarrow P(A) = \frac{3}{8} \cdot \frac{3}{8} = \frac{9}{64} = 14.06\%$$

b) what about without replacement?

$$P(A) = \frac{3}{8} \cdot \frac{2}{7} = \frac{6}{56} = \frac{3}{28} = 10.71\%$$

Example: a personal identification number (PIN) of length 4 is formed by randomly selecting 4 digits from the set of digits  $\{0, 1, 2, \dots, 9\}$ . If selection is done with replacement, find the probability that:

a) The PIN is even:

for the PIN to be even, the last digit must be a multiple of 2.  $\therefore A = \{0, 2, 4, 6, 8\}$ .

$$\therefore P(A) = \frac{n(A)}{N} = \frac{5}{10} = \frac{1}{2} \rightarrow 50\%$$

b) the PIN contains at least one 0?

$$\therefore P(\text{at least one } 0) = 1 - P(\text{no } 0s \text{ in PIN})$$

there are 9 ways to fill each of the digits, as we want the probability of no zeros.

$$\therefore P(\text{no } 0s) = 9 \cdot 9 \cdot 9 \cdot 9 = 9^4 \quad \begin{matrix} \xrightarrow{\text{multiplication counting rule}} \\ \hookrightarrow \text{not } 0 \text{ AND not } 0 \text{ AND...} \end{matrix}$$

total sample space is  $10^4$  (including 0s).

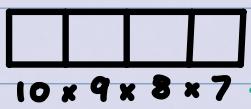

$$\therefore P(\text{at least one zero}) = 1 - \frac{n(\text{no } 0s)}{n(S)} = 1 - \frac{9^4}{10^4}$$

c) Redo a and b but without replacement:

i) even PIN:

A: event of getting an even number.  $\{0, 2, 4, 6, 8\}$ .

S: the sample space

we have less options  
for each digit, bc  
no replacement!

A:  $n(A) = 9 \times 8 \times 7 \times 5$   
 $9 \times 8 \times 7 \times 5 \rightarrow \text{bc } \text{len}(\{0, 2, 4, 6, 8\}) = 5$ .

$$\hookrightarrow P(A) = \frac{9 \times 8 \times 7 \times 5}{10 \times 9 \times 8 \times 7} = \frac{5}{10} = \frac{1}{2} = 50\%$$

ii) at least one zero:

$\curvearrowleft$  no 0 in PIN

$$P(B) = 1 - P(\bar{B}) = 1 - \frac{9 \times 8 \times 7 \times 6}{10 \times 9 \times 8 \times 7} = 1 - \frac{6}{10} = \frac{2}{5} = 40\%$$

Example: a fair die is tossed 3 times. What is the probability that exactly one of the tosses produces a number greater than 4?

let A be the event that the first toss is greater than 4, and the second and third tosses are  $\leq 4$ .

$$\hookrightarrow \{5, 6\}, \{1, 2, 3, 4\}, \{1, 2, 3, 4\}.$$

"AND"  
 $\therefore n(A) = 2 \times 4 \times 4 = 32$ .

let B be the event where the 2<sup>nd</sup> toss is  $> 4$ , and let C be the event where it's the 3<sup>rd</sup> toss.  $\rightarrow n(A) = n(B) = n(C)$

$\therefore$  total number of ways to get exactly one number greater than 4 is  $3(2 \times 4 \times 4) = 96$ .

$$\therefore P(\text{exactly one toss} > 4) = \frac{96}{6^3} = 44.44\%.$$

## Counting Permutations:

- Permutation: an ordered arrangement of a set of objects.

Example: how many different ordered arrangements of the letters a, b, and c are possible?

↳ abc, acb, bac, bca, cab, cba.

∴ 6 arrangements!

This will very quickly become very tedious and slow.

- The number of permutations of n distinguishable objects is:

$$n \times (n-1) \times \dots \times 1 = n!$$

- Given n distinct objects, a permutation of length r is an ordered subset of r objects.

- The number of permutations of length r taken from n objects is denoted as  $n^{(r)}$ , where:

$$n^{(r)} = n \times (n-1) \times \dots \times (n-r+1) = \frac{n!}{(n-r)!}$$

↑ "n to r factors"

Example: five separate awards are to be presented to some students from a class of size 30. How many different outcomes are possible if

a) a student can receive any number of awards?

$$\frac{30}{1^{\text{st}}} \times \frac{30}{2^{\text{nd}}} \times \frac{30}{3^{\text{rd}}} \times \frac{30}{4^{\text{th}}} \times \frac{30}{5^{\text{th}}} = 30^5.$$

$$\therefore n(A) = 30^5$$

b) each student can receive, at most, one award?

$$\frac{30}{1^{\text{st}}} \times \frac{29}{2^{\text{nd}}} \times \frac{28}{3^{\text{rd}}} \times \frac{27}{4^{\text{th}}} \times \frac{26}{5^{\text{th}}} = 30 \cdot 29 \cdot 28 \cdot 27 \cdot 26$$

$$\hookrightarrow n(A) = 30^{(5)} = \frac{30!}{25!}$$

Sometimes the outcomes in the sample space are subsets of a fixed size:

Example: suppose we have three books:  $b_1$ ,  $b_2$ , and  $b_3$ . We choose two of the books to read. In how many ways can the two books be read if:

a) the order that the books are read in matters:

$(b_1, b_2)$ ,  $(b_2, b_1)$

$(b_1, b_3)$ ,  $(b_3, b_1)$  → 6 ways!

$(b_2, b_3)$ ,  $(b_3, b_2)$

b) the order that the books are read in does not matter?

$$\{b_1, b_2\}$$

$$\{b_1, b_3\}$$

$$\{b_2, b_3\}$$

→ 3 ways!

Given  $n$  distinct objects, a combination of size  $r$  is an unordered subset of  $r$  objects chosen from  $n$  distinct objects.

↳ the number of combinations (or subsets) of size  $r$  chosen from  $n$  distinct objects is given by:

$$\binom{n}{r} = \frac{n^{(r)}}{r!} = \frac{n!}{(n-r)r!}$$

↳ "n choose r"

Example: we randomly select a subset of 3 digits from  $\{0, 1, \dots, 9\}$ . All the digits in each outcome are unique, but the order of the elements in a subset is not relevant.

Find the probability that:

a) All the digits in the selected subset are even:

$$S = \{\{0, 1, 2\}, \{0, 1, 3\}, \dots, \{7, 8, 9\}\}$$

$$n(S) = \binom{10}{3}.$$

↗ length of  $S$

the set of even digits is  $\{0, 2, 4, 6, 8\}$ .

let  $A$  be the event that all 3 digits are even.

$$\hookrightarrow n(A) = \binom{5}{3}$$

$$\hookrightarrow P(A) = \frac{n(A)}{n(S)} = \frac{\binom{5}{3}}{\binom{10}{3}} = \frac{1}{12} = 8.3\dot{3}\%$$

b) At least one of the digits in the selected subset is less than or equal to 5.

$$P(\text{at least one digit } \leq 5)$$

$$= 1 - P(\text{no digit } \leq 5)$$

$$= 1 - P(\text{all digits } > 5)$$

the set of digits  $> 5$ :  $\{6, 7, 8, 9\}$ .

$$= 1 - \frac{\binom{4}{3}}{\binom{10}{3}} = \frac{29}{30} = 96.6\dot{6}\%$$

Example: there are 30 geese of which 6 were tagged. Later, 5 of the geese are randomly captured.

a) How many samples of 5 are possible?  $\binom{30}{5}$

b) How many samples of 5, which include 2 of the tagged geese, are possible?

$$\hookrightarrow \binom{6}{2} \cdot \binom{24}{3}$$

c) if the five captured geese represent a simple random sample drawn from the 30

geese, find the probability that:

i) two of the 5 captured geese are tagged.

$$P(A) = \frac{\binom{6}{2} \binom{24}{3}}{\binom{30}{5}} = 0.2130 = 21.3\%$$

ii) none of the 5 captured geese are tagged.

$$P(B) = \frac{\binom{24}{5}}{\binom{30}{5}} = 0.2983 = 29.83\%$$
